**ABSTRACT**

**Aim and objective:** The present report describes an atypical presentation of a lacrimal gland mass in a young male patient. Symptomatology favored a benign mass that was proven to be malignant on histopathology.

**Background:** Adenoid cystic carcinoma is the most common epithelial malignancy of the lacrimal gland. The usual presentation of adenoid cystic carcinoma is in either sex at about an average 40 years of age with range from 6 to 79 years. The patient usually complains of a superotemporal orbital mass with rapid progression usually within a year. Uncommonly, these masses may present with longer history as is described in present case report.

**Case description:** A 17-year-old male patient of Indian origin presented with a mass in the superotemporal part of the right orbit for the last 5 years and 6 months. A firm and smooth orbital mass, approximately 20 mm × 15 mm, was present in superotemporal orbit that was nontender and nonpulsatile. A clinical diagnosis of lacrimal gland pleomorphic adenoma was strongly suggested by the clinical as well as radiological features. The orbital mass was excised en bloc by a right transseptal anterior orbitotomy. Histopathological examination of the excised mass revealed features characteristic of lacrimal gland adenoid cystic carcinoma.

**Conclusion:** Lacrimal gland adenoid cystic carcinoma can simulate pleomorphic adenoma and can present with history over 5 years. Hence, it should always be kept as a clinical possibility in patients with the painless superotemporal orbital mass and early excision of such orbital masses for appropriate diagnosis and management is vital.

**Clinical significance:** The duration of 5½ years at presentation in well-localized lacrimal gland adenoid cystic carcinoma is the longest period ever reported. The present article recommends keeping the differential diagnosis of adenoid cystic carcinoma in all patients with the clinically benign superotemporal orbital mass.

**Keywords:** Adenoid cystic carcinoma, Lacrimal gland, Orbital mass.

**BACKGROUND**

Lacrimal gland epithelial neoplasms are one of most intriguing primary orbital masses. The present report describes an atypical presentation of a lacrimal gland mass in a young male patient. Symptomatology favored a benign mass that was proven to be malignant on histopathology. The patient presented with 5.6 years’ duration of symptoms, which to the best of our knowledge is the longest duration of presentation of well-localized painless lacrimal gland adenoid cystic carcinoma. A literature review of delayed presentations of lacrimal gland adenoid cystic carcinoma is also presented.

**CASE DESCRIPTION**

A 17-year-old male patient of Indian origin presented with a mass in the superotemporal part of the right orbit for the last 5 years and 6 months. The mass was gradually progressive and showed no variation with posture or straining. The patient had no pain, redness, visual complaints, or any other systemic features. Examination revealed right-sided abaxial proptosis of 2 mm (Fig. 1A). A firm and smooth orbital mass, approximately 20 mm × 15 mm, was present in the superotemporal orbit that was nontender and nonpulsatile. The visual acuity was 6/6 in both eyes. A clinical diagnosis of lacrimal gland pleomorphic adenoma was strongly suggested by the clinical as well as radiological features. The mass was pinkish red, firm in consistency, and measured 34 × 22 mm in largest dimensions (Fig. 1C). The intraoperative pattern (Fig. 1D) characteristic of adenoid cystic carcinoma. The orbital mass was excised en bloc by a right transseptal anterior orbitotomy. The mass was pinkish red, firm in consistency, and measured 34 × 30 × 22 mm in largest dimensions (Fig. 1C). The intraoperative and postoperative periods were unremarkable. Histopathological examination of the excised mass revealed multiple lobules formed by malignant cells with pool of mucin forming the Swiss cheese pattern (Fig. 1D) characteristic of adenoid cystic carcinoma. The patient was planned for cytoreductive chemotherapy.

**DISCUSSION**

Lacrimal gland epithelial neoplasms are perhaps the most intriguing primary orbital masses. Adenoid cystic carcinoma is the most common epithelial malignancy of the lacrimal gland. It

An Unusual Lacrimal Gland Mass

accounts for nearly 1.1% of all disorders involving the orbit\(^2\) and 63% of all primary epithelial malignant lacrimal gland masses.\(^1\) The usual presentation of adenoid cystic carcinoma is in either sex at about an average 40 years of age\(^3\) with range from 6 to 79 years.\(^4\) The patient complains of a superotemporal orbital mass with rapid progression usually within a year.\(^5\) However, in few instances the above is not adhered to. In the present patient, long history of a painless anterosuperior orbital mass with no features of malignancy favored a benign pathology. The differential diagnosis included schwannoma, neurofibroma, and solitary fibrous tumor involving the superotemporal part of the orbit. These were considered as the patient presented with signs and symptoms of a painless benign pathology. The radiological features revealed localized well-circumscribed mass with bony fossa formation that also favored a benign pathology. The final diagnosis, however, was adenoid cystic carcinoma. Wright et al. reported their experience with management of patients with adenoid cystic carcinoma. In their series, only one patient had symptoms for more than a year before presentation and all patients except for one had pain.\(^3\) Perez et al. in their series reported the mean time of presentation in adenoid cystic carcinoma to be 26.6 months.\(^6\) The patient with most extensive period of symptomatology prior to presentation in their series had periosteal involvement at presentation and was managed by wide orbital excision.\(^6\) Levartovsky et al. published a case study in 1993 about a female patient who had otherwise asymptomatic lacrimal gland mass for 3 years prior to presentation.\(^7\) The patient was kept under follow-up and the mass became painful after 1 year of presentation. The mass was then biopsied that revealed adenoid cystic carcinoma. The mass was excised and the patient given further required therapy.\(^7\) Wharton and O’Donnell reported a case of an incidentally discovered lacrimal gland mass that underwent excision and was confirmed to be adenoid cystic carcinoma.\(^8\) The authors concluded that adenoid cystic carcinoma may be discovered incidentally in occasional patient.\(^8\)

This report represents the first case of localized painless adenoid cystic carcinoma of the lacrimal gland that presented after 5½ years of onset, which is the longest duration of presentation of well-localized painless adenoid cystic carcinoma to the best of our knowledge. With current practice, pleomorphic adenoma is usually diagnosed preoperatively based on clinical and radiological characteristics. Could it be in situ adenocarcinoma of the lacrimal gland that developed in a long-standing pleomorphic adenoma in the present case remains unanswered. The unusual history and findings in our patient highlight the clinical possibility of the rarer carcinomas with apparently benign course.
Conclusions

Lacrimal gland adenoid cystic carcinoma can simulate pleomorphic adenoma and can present with history over 5 years. Hence, it should always be kept as a clinical possibility in patients with painless superotemporal orbital mass and early excision of such orbital masses for appropriate diagnosis and management is vital.

Clinical Significance

Lacrimal gland masses are among most intriguing primary orbital neoplasms. The present article describes a young male patient who presented with signs and symptoms of long-standing lacrimal gland pleomorphic adenoma that histopathology proved to be adenoid cystic carcinoma. The duration of 5½ years at presentation in well-localized lacrimal gland adenoid cystic carcinoma is the longest period ever reported. The present article recommends keeping the differential diagnosis of adenoid cystic carcinoma in all patients presenting with the clinically benign superotemporal orbital mass.
